Keyword's: Carbamazepine, *Labrys portucalensis* F11, Biodegradation, Degradation pathway, Toxicity

## Background

Occurrence of pharmaceuticals in the environment is a topic of concern. Most pharmaceuticals are not completely mineralized and are released on the sewage systems through excretion and by improper elimination and disposal<sup>(1)</sup>. Municipal wastewater treatment plants (WWTPs) are not designed to remove them and they are released into the environment<sup>(2)</sup>. They are classified as persistent microcontaminants due to their continuous release even if at low concentrations<sup>(3)</sup>. Carbamazepine (CBZ) is an widely used anticonvulsant and has been suggested as a molecular marker of contamination in surface water and groundwater<sup>(4)</sup>.

## Method

Biodegradation of CBZ by the bacterial strain *Labrys portucalensis* F11 was tested as sole carbon and energy source (0.04 mM) and in the presence of acetate as primary carbon source. Transformation products (TPs) were detected and identified by UPLCQTOF/MS/MS. Ecotoxicological effects of CBZ and the TPs resultant from biodegradation were evaluated at different trophic levels, i) zooplankton (*Daphnia magna*) and ii) plants (*Lipidium sativum*). The 24–48 h immobilization of *D. magna* bioassays were performed following the Standard Operational Procedures of Daphtoxkit F™. The toxicity was measured as the immobilization of *D. magna* according to the procedures OECD Guideline 202<sup>(5)</sup>. The bioassay with *L. sativum* evaluated the potential toxicity considering the root elongation according to OECD Guideline 208<sup>(6)</sup>.

## Results & Conclusions

Strain F11 was able to degrade 95% of initial CBZ concentration during 30 days experiment. Supplementation with acetate increased degradation to 100% in 24 days. A group of 12 TPs formed in the microbial process were identified; CBZ degradation by strain F11 proceeds mainly by oxidation, hydroxylation and cleavage of the aromatic ring. The effect of whole biodegradation products on root elongation of *L. sativum* was practically neglectable; however the same exhibited toxicity to *D. magna*. Strain *Labrys portucalensis* F11 proved to be able to degrade CBZ and may be potentially useful for biotechnological applications.
